Ion Channels: New Targets for the Next Generation of Tocolytics Agents

Ion channels are interesting molecules since they mediate not only uterine contraction but also uterine relaxation. We have examined the expression, function, and correlation between the large conductance calcium-activated potassium (BKCa) channel, β2 adrenoceptor (AR), and long-lasting (L) type calcium (Ca2+) channel. These are the main channels and receptor that are involved in the uterine contraction/relaxation process. Our evidence has shown that BKCa channel is closely correlated with β2 AR in mediating uterine relaxation. Both proteins are situated in close proximity on the plasma membrane of human myometrium and are downregulated approximately 50% after the onset of labor. Interestingly, L type Ca2+ channel, which involves in the contraction pathway, seems to be in the same compartmentation as BKCa channel/β2 AR macromolecular complex. Further studies are now being conducted to identify the signaling complex components that could potentially be a target for new tocolytic agents.

Keywords: Ion channel, Preterm, BKCa channel, Pregnancy, Uterus

J Med Assoc Thai 2006; 89 (Suppl 4): S178-83

Preterm birth is a major clinical problem associated with perinatal mortality and serious neonatal morbidity in both developed and developing countries. Despite the number of research that has been performed to find the treatment for preterm labor, the incidence of preterm delivery is still rising. Searching for the safe and effective tocolytic agents is frustrating. This is due to the lack of understanding about the mechanisms that initiate uterine contraction.

Parturition

Labor is a physiologic mechanism when the uterus changes from quiescence state to regular contraction to deliver the baby. Parturition is a multifactorial process involving multiple interconnected positive feed forward, and negative feedback loops. The parturition mechanisms occur as a serial change of myometrium, cervix, and decidua. Once the uterus and cervix are ready, the endocrine, paracrine, and autocrine system will initiate uterine contraction. Unfortunately, we still do not know how these signaling pathways join and how to effectively stop them.

A variety of molecules has been linked to the parturition pathway but we do not know which ones trigger the whole process. We are interested in exploring the functions and roles of ion channels, particularly, potassium (K+) channels and calcium (Ca2+) channels that are the end targets of most signaling pathways and mediate uterine relaxation and contraction,

**Ion channels**

Ion channels are macromolecular protein pores (Fig. 1) in the plasma membrane that allow specific ion to pass in and out the cells e.g., K⁺ channels allow K⁺ ion to pass through, Ca²⁺ channels allow Ca²⁺ ion to pass through, etc. They play an important role in transmitted electrical signal in muscle, nerve and synapse. The unequal distribution of ions across plasma membrane creates cell resting membrane potential. The major ions in the extracellular compartment are sodium (Na⁺) (140 mmol/l), Ca²⁺ (1.5 mmol/l) and chloride (Cl⁻) (135 mmol/l) while K⁺ (150 mmol/l) levels are higher inside the cells. Direction of the current flow is determined by the concentration gradient and the membrane potential difference.

Na⁺ channels have been found in rat and human myometrium. The level of Na⁺ channels in rat myometrium increases shortly before the onset of labor. Cl⁻ channels increase Ca²⁺ entry through Ca²⁺ channels by mediating depolarization causing smooth muscle contraction. The number of Ca²⁺ channels including transient (T) type and long-lasting (L) type Ca²⁺ channels are expressed in myometrium.

Evidence have shown that L type Ca²⁺ channels are progressively increased during pregnancy. K⁺ channels are the largest family of ion channels and are widely distributed in smooth muscle including myometrium and are involved in mediating smooth muscle relaxation.

Our recent studies are concentrated on K⁺ channel, particularly on the large conductance calcium-activated potassium (BKca, Maxi-K) channel, and Ca²⁺ channel, particularly on L type Ca²⁺ channel since they play major roles in mediating relaxation and contraction, respectively. The current guideline by the Royal College of Obstetricians and Gynaecologists (RCOG) also recommends the use of nifedipine, an L type Ca²⁺ channel blocker, as the first line drug for the treatment of preterm labor.

**Fig. 1** Ion channel is a protein pore in the plasma membrane that allows specific ions to pass in and out the cell. (adapted from http://campus.lakeforest.edu/light/teaching.html)
Fig. 2  Figure illustrates both α and β subunit of BK<sub>Ca</sub> channel. S1 – S6 of the α subunit are homologous to voltage-dependent ion channels whereas S7 – S10 are the hydrophobic regions at the carboxy terminus. The β subunit is a modulatory protein which imparts Ca<sup>2+</sup> sensitivity of BK<sub>Ca</sub> channel (adapted from http://www.cf.ac.uk/biosi/staff/jacob/teaching/ionchan/Maxi-K%20channel%20(slo).gif)

Fig. 3  Simplified scheme of the contraction/relaxation mechanisms of pregnant human myometrial cell. Ca<sup>2+</sup> released from sarcoplasmic reticulum (SR) activates influx of Ca<sup>2+</sup> through L type Ca<sup>2+</sup> channel initiating myometrial contractions. Increased intracellular Ca<sup>2+</sup> level is then activates BK<sub>Ca</sub> channel opening leading to uterine relaxation
We have shown that BK$_{Ca}$ channels are predominantly located on the plasma membrane of pregnant human myometrial cells both before and after the onset of labor$^{[18,21]}$. Our results demonstrated that both $\alpha$ and $\beta$ subunits of BK$_{Ca}$ channel proteins are decreased in human after the onset of labor at term$^{[18,21,24]}$. This may be resulted from the changing level of sex steroid hormones during pregnancy$^{[30-32]}$. Downregulation of BK$_{Ca}$ channel at term may allow contraction associated proteins (CAPs), such as oxytocin receptors, Ca$^{2+}$ channels, to enhance myometrial contractility at the onset of labor.

$\beta_2$ adrenoceptor (AR) is the target of ritodrine, a $\beta_2$ AR agonist, which is the only drug that has been approved by the US Food and Drug Administration (FDA) for the management of preterm labor$^{[33]}$. Interestingly, we found that the level of $\beta_2$ AR, which mediated uterine relaxation, is also reduced at the similar level, approximately 50%, after the onset of labor$^{[21,34]}$. Our further study has shown that BK$_{Ca}$ channel and $\beta_2$ AR are closely situated on the plasma membrane of human myometrium$^{[22]}$. Immunoprecipitation study confirmed the protein-protein association between both of them whereas pharmacological and electrophysiological studies demonstrated their functional association$^{[22,23]}$.

This evidence suggested that BK$_{Ca}$ channel and $\beta_2$ AR form a macromolecular complex and may be involved in the same signaling cascade which controls the uterine excitability and may have direct interaction between these two proteins (Fig. 3). Interestingly, our recent experiments suggested that L type Ca$^{2+}$ channel, which is one of the contraction associated proteins (CAPs) is also a member of the same compartmentation with BK$_{Ca}$ channel/ $\beta_2$ AR macromolecular complex (personal communication). Further studies are underway to examine the mechanisms that regulate BK$_{Ca}$ channel/ $\beta_2$ AR/ L type Ca$^{2+}$ channel macromolecular complex in pregnant human myometrial cells.

**Conclusion**

More effective and more selective tocolytic agents are urgently needed. The high rate of mortality, short and long term morbidity causing by preterm delivery have a significant impact not only on health care but also on education, social, and families. The consequences of preterm birth continue beyond neonatal period and have both direct and indirect impact on parents and society. Evidence has suggested that BK$_{Ca}$ channel/ $\beta_2$ AR/ L type Ca$^{2+}$ channel macromolecular complex in pregnant human myometrial cells may play a major role in regulating uterine (in) excitability. Further studies are needed to examine this compartmentation in more details. The component of this signaling complex including second messengers, anchoring proteins and effectors may be the potential target for the next generation of tocolytic agents. Multidisciplinary approach is essential for complete understanding of the mechanism of uterine contraction. Knowledge from basic sciences research needs to be translated to clinical trials in order to develop and improve clinical care for preterm labor.
